

MKDA density, NiMARE default kernel, FDR-independent correction; maps regenerated identically for every arm.

R^2 is over an MNI152 brain mask. The repo's convention correlates every finite voxel, which on these sparse maps is 88-96% voxels that are zero in both and inflates R^2 by roughly 0.05; restricting further to voxels nonzero in either map roughly halves it again (see `record_arms_meta_metrics.csv`).

Panel b averages each project's mapped analyses, counted under its label, and offsets the arms horizontally so coincident points stay visible.

No mapped analysis comes from a paper its own arm rejected. Cue reactivity, dementia and VBM PTSD annotate from each arm's own document; VBM substance use annotates from title and abstract only, because its full-text arm's articles are not on this host.

Re-running one project's annotation unchanged moved its arms by 0.034 R^2 , which exceeds several of the between-arm gaps shown here.
