

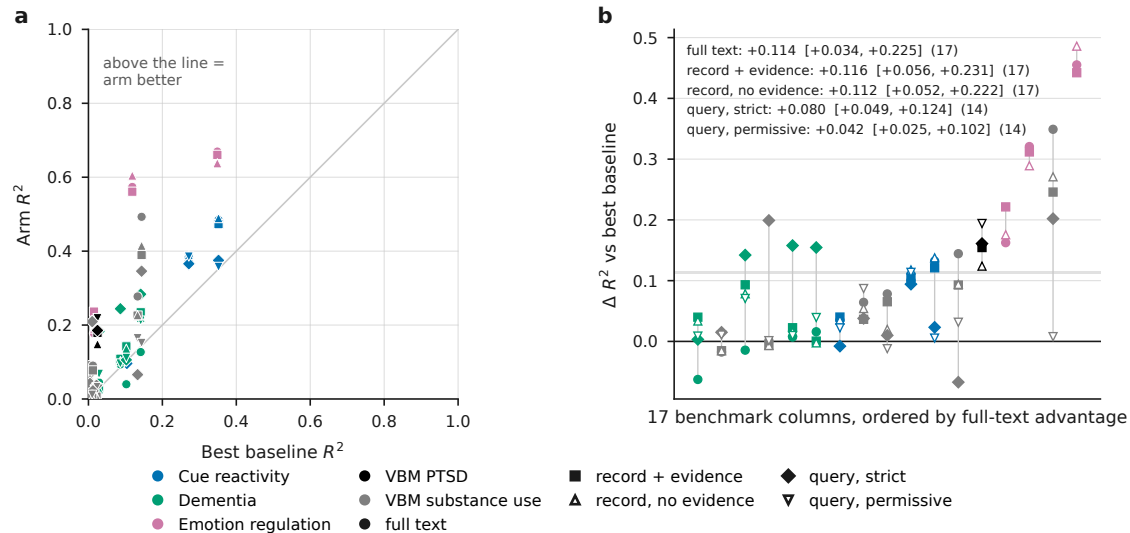

Figure 4's comparison, per arm, over the 17 columns whose projects have record arms. Baselines are re-estimated from their own studysets with the settings the arms used, because the committed baseline table came from a different estimator. Both sides use `r2_nonzero`. CI is a percentile bootstrap resampling projects, not columns.

Colour is the project and shape is the arm in both panels; the grey band in b spans the three model arm means, which differ by 0.004. The query arms are predicates over the record rather than a model, and are scored on the columns where they map at least 5 analyses; n per arm is in brackets.
